ABSTRACT

Studies show that the degree to which children are physically active is a good predictor of overall fitness. Simple wearable devices can measure this quantity fairly accurately. However, children need more incentive than simple activity tracking to encourage them to be active and healthy. We propose that participation in game narratives provides such incentive. We have built a wearable device with which children can play an engaging transmedia collection game called Time Tremors. Physical encouragement is integrated into the game narrative so that children participate unselfconsciously and engage kinaesthetically with narratives, artifacts and cultural venues.

INTRODUCTION

This work concerns the intersection of transmedia game design and wearables that encourage activity in children. Game-playing is a popular and time-consuming pastime for many children. Most child-oriented games, even those played on wearables, encourage sedentary play. Some would argue that widespread yet sedentary game-play is a threat to the fitness of children. Games and game-oriented wearables should not decrease the health or fitness to whom they are marketed. Gaming for children should at least reach the threshold of 'do no harm'.

Wearables with their many sensors and rich potential as gaming platforms can be designed in to encourage

movement in their wearers. The issue is how to encourage movement in a way that will work both in the short and long term. Activity, if it is to have an effect on fitness, must entail some degree of long-term behavioural change. This is a tall order for wearables whose likely lifespan may be short.

Activity tracking wearables usually assume implicitly that representation of activity patterns will provide sufficient motivation to improve overall fitness. The idea is that if you see graphically how your behaviour is changing then you will be motivated to continue your process of improvement. This may be true for some but as a recipe for fitness improvement for a population who have various motivations it appears naive. Greater activity has to be connected to some additional goal beyond representation that the player finds meaningful. Our approach is to integrate player movement with the exploration of transmedia narratives. We believe that narratives in their many forms have the depth and power to motivate behaviour. The behavioural modification implied by building healthy games and wearables for children need not be explicit. If the game narrative is designed in such a way that player movement is an organic aspect of the story then connecting player movement to game play does not become intrusive.

THE TRANSMEDIA GAMING ENVIRONMENT OF TIME TREMORS

Many children enjoy playing games. The reason that spend so much time playing them is that they find them engaging and fun. Our device works in conjunction with a transmedia and location-based game called Time Tremors. Being a transmedia game, Time Tremors can be viewed on several platforms including TV, and on-line on computers, smart phones and tablets. Transmedia is that which spans multiple devices and media channels [?]. These narratives are authored by writers intentionally, with explicit and carefully engineered connection points between media platforms. Despite these transition points, the integrity of the narrative must remain intact. To continue viewing or participating in the narrative, the viewer has the opportunity to switch devices without losing the narrative thread. The transmedia narrative connection adds engagement for the player

to an interaction with a wearable. Increased physical activity is an intended side effect of playing the game. Compared to how sedentary behaviour is an unintended side effect of playing most other games.

THE PROMISE OF 'EXERGAMES'

Exergames are ones that encourage or require movement in their players. In order to work they both have to be shown to actually require physical activity, and they also have to be adequately engaging and interesting to provide incentive for people to play them [5]. Activity that is expected to have a significant fitness effect tends to be rather strenuous and take place over a long period. The results of a new exercise regime may take months to appear. An effective exergame must encourage people to start moving more and it must be sufficiently interesting for people to continue working at it. Like gym memberships, the novelty of exercising with or without a device often wears off quickly. This is a rather difficult standard for a game or device to achieve: work as real exercise and sufficiently motivate people to use and benefit from them. The most prominent examples of exergames are those played on the Nintendo Wii.

Whitehall, et al. surveyed the number of calories expended while playing exergames and found that there is a wide range of values. Some are quite effective while others do very little [5]. Typically, these games are marketed towards children who find them fun to play. There is also a large market for exergames tailored towards the elderly, where the negative effects of sedentary lifestyles are even more problematic than with children [4].

There is a strong correlation between heart rate and energy expenditure [5]. Activities that engage the whole body tend to be more effective for fitness than ones that engage individual limbs [2]. One way of encouraging whole body movement is to attach several sensors to player's limbs. Some exergames (e.g. Wii) allow pseudo-movement: minor movement read incorrectly by device sensors as major body movement. Exergames should be designed to prevent this kind of 'cheating'. Measuring more aspects of activity, such as body and limb movement, and heart rate more accurately measures real activity that will likely have a real effect on fitness.

TIME TREMORS COLLECTION GAME

Our device is an device that enables the child to interact and play with the transmedia, location and collection-based game called Time Tremors. Time Tremors is a collection-type game. Children collect virtual artifacts that they discover while on location-based treasure hunts in museums, and other venues. Children must maintain a level of a game-specific quantity called 'time energy'. Time energy is gathered as one maintains a level of physical activity while wearing the device. If the player has sufficient time energy players are able to collect 'time treasures'. Time treasures are the item collected within the game. If sufficient treasures are collected, in certain

combinations, then other opportunities to collect additional treasures are presented to the player. There is also a transmedia connection in that players can collect treasures while watching TV episodes connected to the game, navigating successfully through a flying game, or solving puzzles.

OUR WEARABLE WRIST DEVICE

Our device is a wrist wearable that incorporates a wireless bluetooth microprocessor, an electrocardiogram (ECG) type heart sensor and an accelerometer that measures movement and accelerative forces. Accelerometers that measure acceleration in three axes are common in wearables to measure activity of various types [1]. The purpose for using these two sensors working together is to get a composite measure that indicates the overall physical activity of the child wearing the device. The player needs to have a heart rate above a certain threshold and also have physical movement measured by the device's accelerometer above a certain level.

BIOMETRICS ON WEARABLES

Measuring biometrics is an area of increasing interest, especially in the medical fields. Biosensors measure physiological parameters like blood pressure, heart rate, oxygen saturation of the blood, respiration rate, electrical muscle activity in limbs and the heart, body and skin temperature, etc. This technology is expected to have a major effect on real-time monitoring of health and fitness for personal information and medical diagnostic purposes [3]. This technology is particularly suitable for monitoring patients outside of hospitals at their homes as they go about their normal routines. In non-medical situations biometric sensors are also useful in games in which activity, fitness and movement play a role.

GAMES ON WRIST WEARABLES

Wrist wearables are typically small devices on which normal touch interfaces are typically problematic due to their small size. Using the device as part of a hand gesture recognition system overcomes the small size limitation [?]. Our device is used a simple platform for displaying the degree of physical activity of the player and a housing for the sensors (the accelerometer and heart rate sensor) that measure this activity.

CONCLUSION

Children spend an inordinately large number of hours playing games. One approach to increasing the value of this time spent is to convert some of them into so-called 'exergames'. This type of game has the promise of increasing activity and fitness in the children who play them. It is not difficult to engage children in a game for short period of time. However, healthy habits with respect to activity requires a long-term commitment and high levels of physically and intellectual engagement. Our approach is to integrate and to increase the engagement of players using the device of transmedia gaming. The narrative appeal of transmedia should

increase the incentive of physical activity, not by the appeal of heightened fitness, but by the desire of players to explore narratives.
